

/ Descriptions

The BRCM24C64SC is 64Kbit I²C-compatible Serial EEPROM (Electrically Erasable Programmable Read-Only Memory) device in a SOP-8 Plastic Package. Halogen-free Product.

/ Features

Single Supply Voltage

Minimum operating voltage down to 1.7V 1 MHz clock from 2.5V to 5.5V 400kHz clock from 1.7V to 2.5V

Low power CMOS technology Read current 400uA, maximum Write current 1.6mA, maximum Schmitt Trigger, Filtered Inputs for Noise Suppression

Sequential & Random Read Features

32-byte Page Write Modes

Write protect of the whole memory array

Additional Write Lockable Page and 128-bit Serial Number

Self-timed Write Cycle (5ms maximum)

High Reliability Endurance: > 1 Million Write Cycles Data Retention: > 100 Years HBM: 6KV

Latch up Capability: +/-200mA;

/ Applications

Household appliances, Network communications, Portable Bluetooth devices, Set-top boxes, Smart meters, Fingerprint unlocking devices

/ Pinning

/ Pinning

/ Marking

/ See Marking Instructions

/ Absolute Maximum Ratings(Ta=25)

Parameter	Symbol	Rating	Unit
Storage Temperature	T _{stg}	-65~+150	
Operation Temperature	T _{opr}	-40~+85	
Maximum Operation Voltage	V _{cc}	6.25	V
Voltage on Any Pin with Respect to Ground	V _{pin}	-1.0~ V _{cc} +1.0	V
DC Output Current	I _{out}	5.0	
Electro-Static discharge HBM mode	ESD	6000	

/ Reliability Characteristic

Parameter	Symbol	Test Conditions	Min	Typ	Max	Unit
Endurance	EDR	25 3.3V Page mode	1,000,000			Write cycles
Data retention	DRET		100			Years

/ AC Electrical Characteristics(Unless otherwise specified, Vcc = 1.7V to 5.5V,

T_A = -40°C to 85 F

Parameter	Symbol	1.7V Vcc<2.5V			2.5V Vcc 5.5V			Unit
		Min	Typ	Max	Min	Typ	Max	
Data In Hold Time	t _{HD.DAT}	0	-	-	0	-	-	us

Data Out Hold Time	t _{DH}	0.05	-	-	0.05	-	-	us
WCB pin Setup Time	t _{SU.WCB}	1.2	-	-	0.6	-	-	us
WCB pin Hold Time	t _{HD.WCB}	1.2	-	-	0.6	-	-	us
Write Cycle Time	t _{WR}	-	-	5	-	-	5	ms

Notes:AC measurement conditions:

1. R_L (connects to Vcc): 1.3k (2.5V, 5.5V), 10k (1.7V)
2. Input pulse voltages: 0.3 Vcc to 0.7 Vcc
3. Input rise and fall times: 50ns
4. Input and output timing reference voltages: 0.5Vcc

/ Functional Description

/ Data Input

The SDA pin is normally pulled high with an external device. Data on the SDA pin may change only during SCL low time periods (see to Figure 1). Data changes during SCL high periods will indicate a start or stop condition as defined below.

/ Start Condition

A high-to-low transition of SDA with SCL high is a start condition which must precede any other command (see to Figure 2)

/ Stop Condition

A low-to-high transition of SDA with SCL high is a stop condition. After a read sequence, the stop command will place the BRCM24C64SC in a standby power mode (see Figure 2).

ACK / Acknowledge

/ Functional Description

All addresses and data words are serially transmitted to and from the BRCM24C64SC in 8-bit words. The BRCM24C64SC sends a “0” to acknowledge that it has received each word. This happens during the ninth clock cycle.

/ Standby Mode

The BRCM24C64SC features a low-power standby mode which is enabled: (a) after a fresh power up, (b) after receiving a STOP bit in read mode, and (c) after completing a self-time internal programming operation.

/ Soft Reset

After an interruption in protocol, power loss or system reset, any two-wire part can be reset by following these steps: (a) Create a start condition, (b) Clock nine cycles, and (c) create another start bit followed by stop bit condition, as Figure 4 . The device is ready for the next communication after the above steps have been completed.

/ Device Addressing

The BRCM24C64SC requires an 8-bit device address word following a start condition to enable the chip for a read or write operation (see table 1). The device address word consists.

/ Functional Description

Chip	Access area	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

	Serial Number	X	X	X	X	A3	A2	A1	A0

Table 3 Second Word Address

The E2, E1 and E0 device address bits to allow as many as 8 devices on the same bus. These bits must compare to their corresponding hardwired input pins. The E2, E1 and E0 pins use an internal proprietary circuit that biases them to a logic low condition if the pins are floating. The eighth bit of the device address is the read/write operation select bit. A read operation is initiated if this bit is high and a write operation is initiated if this bit is low. Upon a compare of the device address, the Chip will output a zero. If a compare is not made, the device will return to a standby state.

/ Data Security

BRCM24C64SC has a hardware data protection scheme that allows the user to write protect the whole memory when the WCB pin is at Vcc.

/ Byte Write

/ Functional Description

A write operation requires one 8-bit data word address A12/A0 following the device address word and acknowledgment. Upon receipt of this address, the BRCM24C64SC will again respond with a “0” and then clock in the first 8-bit data word. Following receipt of the 8-bit data word, the BRCM24C64SC will output a “0” and the addressing device, such as a microcontroller, must terminate the write sequence with a stop condition. And then the BRCM24C64SC enters an internally timed write cycle, all inputs are disabled during this write cycle and the BRCM24C64SC will not respond until the write is complete (see Figure 5).

Notes: [1] x means don't care.

Figure 5 Byte Write

/ Page Write

A page write is initiated the same as a byte write, but the master does not send a stop condition after the first data word is clocked in. Instead, after the BRCM24C64SC acknowledges receipt of the first data word, the master can transmit more data words. The BRCM24C64SC will respond with a “0” after each data word received. The microcontroller must terminate the page write sequence with a stop condition.

Figure 6 Page Write

/ Functional Description

The lower five bits of the data word address are

/ Functional Description

The Lock Identification Page instruction (Lock ID) permanently locks the Identification page in Read-only mode. The Lock ID instruction is similar to Byte Write (into memory array) with the following specific conditions:

- (a) Device type identifier = 1011b.
- (b) Address bit A10 must be '1' all other address bits are don't care.
- (c) The data byte must be equal to the binary value xxxx xx1x, where x is don't care.

/ Read Operations

Read operations are initiated the same way as write operations with the exception that the read/write select bit in the device address word is set to "1". There are three read operations: Current Address Read; Random Address Read and Sequential Read.

/ Current Address Read

The internal data word address counter maintains the last address accessed during the last read or write operation, incremented by one. This address stays valid between operations as long as the chip power is maintained. The address roll-over during read is from the last byte of the last memory page to the first byte of the first page. Once the device address with the read/write select bit set to "1" is clocked in and acknowledged by the BRCM24C64SC, the current address data word is serially clocked out. The microcontroller does not respond with an input "0" but does generate a following stop condition (see Figure7).

Current Address Read

/ Random Address Read

/ Functional Description

A Random Read requires a “dummy” byte write sequence to load in the data word address. Once the device address word and data word address are clocked in and acknowledged by the BRCM24C64SC, the microcontroller must generate another start condition. The microcontroller now initiates a Current Address Read by sending a device address with the read/write select bit high. The BRCM24C64SC acknowledges the device address and serially clocks out the data word. The microcontroller does not respond with a “0” but does generate a following stop condition (see Figure 8).

/ Sequential Read

Sequential Reads are initiated by either a Current Address Read or a Random Address Read. After the microcontroller receives a data word, it responds with acknowledge. As long as the BRCM24C64SC receives acknowledge, it will continue to increment the data word address and serially clock out sequential data words. When the memory address limit is reached, the data word address will roll-over and the Sequential Read will continue. The Sequential Read operation is terminated when the microcontroller does not respond with a “0” but does generate a following stop condition (see Figure 9).

/ Functional Description

/ Read Identification Page

The Identification Page (32 bytes) is an additional page which can be written and (later) permanently locked in Read-only mode. The Identification Page can be read by Read Identification Page instruction which uses the same protocol and format as the Read Command (from memory array) with device type identifier defined as 1011b. The MSB address bits A12/A5 are don't care, the LSB address bits A4/A0 define the byte address inside the Identification Page. The number of bytes to read in the ID page must not exceed the page boundary (e.g. when reading the Identification Page from location 10d, the number of bytes should be less than or equal to 22, as the ID page boundary is 32 bytes).

/ Read the Lock Status

The locked/unlocked status of the Identification page can be checked by transmitting a specific truncated command [Identification Page Write instruction + one data byte] to the device. The device returns an acknowledge bit if the Identification page is unlocked, otherwise a NoACK bit if the Identification page is locked (see Figure 10).

/ Read Serial Number

/ Functional Description

Reading the serial number is similar to the sequential read sequence but requires use of the device address seen in Table 1 , a dummy write, and the use of a specific word address. The entire 128-bit value must be read from the starting address of the serial number block to guarantee a unique number.

Since the address pointer of the device is shared between the regular EEPROM array and the serial number block, a dummy write sequence, as part of a Random Read or Sequential Read protocol, should be performed to ensure the address pointer is set to zero. A Current Address Read of the serial number block is supported but if the previous operation was to the EEPROM array, the address pointer will retain the last location accessed, incremented by one. Reading the serial number from a location other than the first address of the block will not result in a unique serial number.

Additionally, the word address contains a 10 sequence in bit A11 and A10 of the word address, regardless of the intended address as depicted in Table 2 . If a word address other than 10 is used, then the device will output undefined data.

Example: If the application desires to read the first byte of the serial number, the word address input would need to be 0800h.

When the end of the 128-bit serial number is reached (16 bytes of data), continued reading of the extended memory region will result in repeated serial number data readout for the data word address will roll-over back to the beginning of the 128-bit serial number. The Serial Number Read operation is terminated when the microcontroller does not respond with a zero (ACK) and instead issues a Stop condition (see Figure 11)

/ Time Sequence Diagram

Bus Timing

Write Cycle Timing

cycle time t_{WC} is the time from a valid stop condition of a write sequence to the end of the internal clock/write-cycle.
